***Abstract*—This undergraduate thesis investigates an Android application for selling electronic devices through web services. An electronics catalogue needs product discovery and administrative records that can be accessed from a mobile device. The student specifies use cases and system diagrams, designs a database, and implements an Android application connected to web services for product, news, and reporting functions. The thesis presents application screens and reports product search, product information, and management functions in the student prototype. The conclusion says some functions, including product viewing and customer support, remain incomplete. It does not provide independent evidence of secure payments, live transactions, or production-scale use. The contribution is a documented student study or prototype whose stated scope can guide further testing.**

***Index Terms*—Android, web services, electronics sales, product management**

I. Introduction

An electronics catalogue needs product discovery and administrative records that can be accessed from a mobile device. This thesis investigates an Android application for selling electronic devices through web services. It begins from a practical engineering need and explains the technologies and workflow chosen for the case. The objective is to document a student implementation or comparative investigation, together with the evidence available in the manuscript. Broader operational or economic effects require separate measurements and are not assumed from the existence of a prototype [1]. Earlier ICTU student work on related designs is included here for context [2], [3], [4], [5], [6], [7], [8], [9], [10]. These contextual works were selected for this English summary; they are not asserted to appear in the original thesis bibliography.

II. Methods

The student specifies use cases and system diagrams, designs a database, and implements an Android application connected to web services for product, news, and reporting functions. The source is summarized through its stated design, implementation material, examples, and conclusion. Features shown in the manuscript are distinguished from proposals for later development. This review does not add a new experiment, fill missing measurements with estimates, or treat a planned capability as an observed result. The source thesis remains the provenance for the reported work [1].

Supervisor: Mai Văn Hoàn, Thai Nguyen University of Information and Communication Technology (mvhoan@ictu.edu.vn).

III. Results

The thesis presents application screens and reports product search, product information, and management functions in the student prototype. The report's screens, configurations, examples, or measurements constitute the evidence for this summary. A capability described only as a design intention is not counted as a validated operational outcome. No additional performance, adoption, financial, or safety figure has been introduced here. The result is interpreted within the scope of the student's documented setup [1].

IV. Discussion

The conclusion says some functions, including product viewing and customer support, remain incomplete. It does not provide independent evidence of secure payments, live transactions, or production-scale use. Further work could complete the unfinished screens, test service security and transaction flows, and evaluate usability with actual customers. These limitations affect how the evidence should be read. The current manuscript can support understanding of the design and reported demonstration, while independent tests would be needed for stronger claims. Any later deployment should document its environment and separate observed outcomes from intended benefits [1].

V. Conclusion

The thesis documents an Android application for selling electronic devices through web services. The thesis presents application screens and reports product search, product information, and management functions in the student prototype. The conclusion says some functions, including product viewing and customer support, remain incomplete. It does not provide independent evidence of secure payments, live transactions, or production-scale use. Further work could complete the unfinished screens, test service security and transaction flows, and evaluate usability with actual customers. Accordingly, the present contribution is a source-grounded account of the student work and its tested or illustrated scope. Claims about broader effectiveness should be assessed in later work using explicit evaluation conditions [1].
