***Abstract*—This undergraduate thesis investigates a weather information application with an assistant-style interaction. Users often need a convenient way to request current conditions and forecast information for a selected location. The thesis describes a weather website that obtains information from the OpenWeatherMap interface. It also presents the design of an assistant interaction and illustrates the application pages and data flow. The report documents the weather-information interface and an assistant-oriented design. The source supports presentation and retrieval of external weather data; it does not establish that the application produced forecasts independently or improved forecast accuracy. Because data comes from an external service, its availability and quality affect the application. The manuscript does not provide a controlled usability study, high-load test, or independent accuracy comparison. The contribution is a documented student study or prototype whose stated scope can guide further testing.**

***Index Terms*—weather application, virtual assistant, OpenWeatherMap, web interface**

I. Introduction

Users often need a convenient way to request current conditions and forecast information for a selected location. This thesis investigates a weather information application with an assistant-style interaction. It begins from a practical engineering need and explains the technologies and workflow chosen for the case. The objective is to document a student implementation or comparative investigation, together with the evidence available in the manuscript. Broader operational or economic effects require separate measurements and are not assumed from the existence of a prototype [1]. Related published studies provide context for the subject and methods [2], [3], [4], [5], [6], [7], [8], [9], [10]. These contextual works were selected for this English summary; they are not asserted to appear in the original thesis bibliography.

II. Methods

The thesis describes a weather website that obtains information from the OpenWeatherMap interface. It also presents the design of an assistant interaction and illustrates the application pages and data flow. The source is summarized through its stated design, implementation material, examples, and conclusion. Features shown in the manuscript are distinguished from proposals for later development. This review does not add a new experiment, fill missing measurements with estimates, or treat a planned capability as an observed result. The source thesis remains the provenance for the reported work [1].

Supervisor: Vũ Vinh Quang, Thai Nguyen University of Information and Communication Technology (vvquang@ictu.edu.vn).

III. Results

The report documents the weather-information interface and an assistant-oriented design. The source supports presentation and retrieval of external weather data; it does not establish that the application produced forecasts independently or improved forecast accuracy. The report's screens, configurations, examples, or measurements constitute the evidence for this summary. A capability described only as a design intention is not counted as a validated operational outcome. No additional performance, adoption, financial, or safety figure has been introduced here. The result is interpreted within the scope of the student's documented setup [1].

IV. Discussion

Because data comes from an external service, its availability and quality affect the application. The manuscript does not provide a controlled usability study, high-load test, or independent accuracy comparison. Further work could test assistant question coverage, accessibility, error behavior when the weather service is unavailable, and user understanding of forecast uncertainty. These limitations affect how the evidence should be read. The current manuscript can support understanding of the design and reported demonstration, while independent tests would be needed for stronger claims. Any later deployment should document its environment and separate observed outcomes from intended benefits [1].

V. Conclusion

The thesis documents a weather information application with an assistant-style interaction. The report documents the weather-information interface and an assistant-oriented design. The source supports presentation and retrieval of external weather data; it does not establish that the application produced forecasts independently or improved forecast accuracy. Because data comes from an external service, its availability and quality affect the application. The manuscript does not provide a controlled usability study, high-load test, or independent accuracy comparison. Further work could test assistant question coverage, accessibility, error behavior when the weather service is unavailable, and user understanding of

forecast uncertainty. Accordingly, the present contribution is a source-grounded account of the student work and its tested or illustrated scope. Claims about broader effectiveness should be assessed in later work using explicit evaluation conditions [1].
