***Abstract*—This undergraduate thesis investigates an online clinic appointment-booking website. Patients and clinics need a clear way to request and manage appointments. The student analyses clinic booking requirements, designs a database in SQL Server, and implements website functions for the proposed workflow. The thesis documents screens, design material, and tests using some assumed data. The conclusion reports that the principal functions were implemented and operated in the student test setting. It also states that notification and hotline functions were unfinished, some data were hypothetical, and security and business-process analysis were incomplete. The source does not document live clinical deployment, verified patient bookings, or a privacy and security review suitable for sensitive appointment information. The contribution is a documented student study or prototype whose stated scope can guide further testing.**

***Index Terms*—clinic booking, appointment website, SQL Server, healthcare software**

I. Introduction

Patients and clinics need a clear way to request and manage appointments. This thesis investigates an online clinic appointment-booking website. It begins from a practical engineering need and explains the technologies and workflow chosen for the case. The objective is to document a student implementation or comparative investigation, together with the evidence available in the manuscript. Broader operational or economic effects require separate measurements and are not assumed from the existence of a prototype [1]. Earlier ICTU student work on related designs is included here for context [2]. Related published studies provide context for the subject and methods [3], [4], [5], [6], [7], [8], [9], [10]. These contextual works were selected for this English summary; they are not asserted to appear in the original thesis bibliography.

II. Methods

The student analyses clinic booking requirements, designs a database in SQL Server, and implements website functions for the proposed workflow. The thesis documents screens, design material, and tests using some assumed data. The source is summarized through its stated design, implementation material, examples, and conclusion. Features shown in the manuscript are distinguished from proposals for later development. This review does not add a new experiment, fill missing measurements with estimates, or treat a planned capability as an observed result. The source thesis remains the provenance for the reported work [1].

Supervisor: Nguyễn Thu Phương, Thai Nguyen University of Information and Communication Technology (ntphuong@ictu.edu.vn).

III. Results

The conclusion reports that the principal functions were implemented and operated in the student test setting. It also states that notification and hotline functions were unfinished, some data were hypothetical, and security and business-process analysis were incomplete. The report's screens, configurations, examples, or measurements constitute the evidence for this summary. A capability described only as a design intention is not counted as a validated operational outcome. No additional performance, adoption, financial, or safety figure has been introduced here. The result is interpreted within the scope of the student's documented setup [1].

IV. Discussion

The source does not document live clinical deployment, verified patient bookings, or a privacy and security review suitable for sensitive appointment information. Further work could complete notifications, validate the workflow with a clinic, and test access control and data protection before any real patient use. These limitations affect how the evidence should be read. The current manuscript can support understanding of the design and reported demonstration, while independent tests would be needed for stronger claims. Any later deployment should document its environment and separate observed outcomes from intended benefits [1].

V. Conclusion

The thesis documents an online clinic appointment-booking website. The conclusion reports that the principal functions were implemented and operated in the student test setting. It also states that notification and hotline functions were unfinished, some data were hypothetical, and security and business-process analysis were incomplete. The source does not document live clinical deployment, verified patient bookings, or a privacy and security review suitable for sensitive appointment information. Further work could complete notifications, validate the workflow with a clinic, and test access control and data protection before any real patient use. Accordingly, the present contribution is a source-grounded account of the student work and its tested or illustrated scope. Claims about broader effectiveness should be assessed in later work using explicit evaluation conditions [1].
