***Abstract*—This thesis explores the Service-Oriented Architecture (SOA) and Web Services, focusing on their application in Geographic Information Systems (GIS). It provides an overview of SOA, Web Services, and their benefits, and discusses the implementation of Web Services in GIS applications. The research highlights the potential of SOA and Web Services in addressing complex software development challenges and suggests they will be strategic foundations for future applications. The study also examines the current state of software development, the benefits and challenges of SOA and Web Services, and their practical application in GIS. The implemented WebGIS application demonstrates the feasibility of integrating these technologies, although it has limitations in terms of functionality and performance.**

***Index Terms*—Service-Oriented Architecture, Web Services, Geographic Information Systems, GIS, WebGIS, SOA**

I. Introduction

The thesis aims to investigate the Service-Oriented Architecture (SOA) and Web Services, particularly their application in Geographic Information Systems (GIS). It addresses the increasing complexity of software development and the need for more efficient and professional software solutions. The research covers the current state of software development, the benefits and challenges of SOA and Web Services, and their implementation in GIS applications. The study is structured into three chapters, each focusing on different aspects of SOA and Web Services, and their practical application in GIS [1]. Published books on the methods and subject of this project provide context for this English summary [8]. Published articles on the methods and subject of this project provide context for this English summary [9], [10], [11], [12].

II. Methods

The study involves a comprehensive review of existing literature on SOA and Web Services, including books and academic papers. It also includes the development of a WebGIS application to demonstrate the practical application of these technologies in GIS. The WebGIS application was built using JSP, HTML, JavaScript, and XML, and it integrates Web Map Service (WMS) and Web Feature Service (WFS) functionalities. The implementation process involved defining the system architecture, developing the application, and testing its performance and functionality [1].

Supervisor: ICTU Teacher 114, Thai Nguyen University of Information and Communication Technology.

III. Results

The research concludes that SOA and Web Services offer a robust solution for complex software development challenges, particularly in GIS applications. The developed WebGIS application demonstrates the feasibility of integrating these technologies, although it is noted that the application has limitations in terms of functionality and performance. The application supports basic functionalities such as zooming, panning, and layer switching, but it struggles with large datasets and complex queries. The study also highlights the need for more advanced data management and performance optimization techniques [1].

IV. Discussion

The thesis discusses the advantages of SOA and Web Services, such as modularity, reusability, and scalability, and their potential to address the increasing complexity of software development. It also identifies limitations, such as the need for more advanced data management and the performance issues with large datasets. The implemented WebGIS application serves as a proof of concept, showing that SOA and Web Services can be effectively integrated into GIS applications. However, the application's limitations suggest that further development is needed to fully realize their potential, particularly in terms of data management and performance optimization [1].

V. Conclusion

The research suggests that SOA and Web Services are promising solutions for future software development, especially in GIS applications. However, further development is needed to fully realize their potential, particularly in terms of data management and performance optimization. The implemented WebGIS application demonstrates the feasibility of integrating these technologies, but it has limitations in terms of functionality and performance. The study highlights the need for more advanced data management techniques and performance optimization to address the challenges of large datasets and complex queries [1].
